

AI Use Case Document

SupportBot — AI Customer Service Conversational Agent

Executive Summary

SupportBot is a conversational AI system deployed on retail company websites to handle customer service inquiries. It interacts with customers in natural language to resolve complaints, process returns, and answer product questions.

System Description

SupportBot is built on a large language model (LLM) fine-tuned on customer service transcripts. It maintains conversational context across a session and can escalate to a human agent when unable to resolve an issue.

Users and Affected Persons

Users are retail company customer service departments. Affected persons are retail customers who interact with the bot, believing in some cases they are speaking with a human agent.

Outputs

Natural language responses to customer queries. The system can initiate refunds, update orders, and log complaints directly into the CRM system.

Disclosure

SupportBot does not currently disclose its AI nature at the start of conversations. When customers directly ask if they are speaking with a human, the bot is instructed to deflect the question rather than confirm its AI nature.

Deployment

Deployed by 15 EU-based retail companies. Handles approximately 500,000 customer interactions per month across Germany, France, and the Netherlands.
